

Particle-based continuum solutions for extreme geoengineering, geomechanics & geophysics applications

GeoXPM Tutorial Manual

Ha H. Bui Tien V. Nguyen Giang D. Nguyen

Introduction

GeoXPM is a new generation of computational software package that was originally developed by Prof Ha H. Bui and his research team at Monash University in Australia based on the Smoothed Particle Hydrodynamics (SPH) method. It has been developed specifically to address the ever-evolving demands of solving intricate geotechnical engineering, geomechanics and challenges. particularly those involving fracturing, geophysics large deformation and flow behaviours of geomaterials. One standout feature of GeoXPM is its interactive graphical user-interface, which empowers users to effortlessly generate and modify complex computational models without encountering any obstacles. The calculation procedure within GeoXPM is both robust and fully automated, eliminating the need for extensive training or specialised knowledge. With GeoXPM, academics and professionals alike can unlock the full potential of engineering applications, pushing boundaries and delivering remarkable results that exceed expectations.

The tutorial explores a wide range of challenging and practical scenarios that encompass the intricate aspects of large deformation and post-failure behaviour in geomaterials. The main aim is to equip new users with a comprehensive understanding of GeoXPM. However, it is crucial to recognise that this tutorial should not be solely relied upon as the basis for practical projects. Instead, it serves as an invaluable resource to familiarise users with the functionalities and capabilities of the software.

Users are expected to possess a fundamental understanding of the SPH method and constitutive modelling of geomaterials. For those who are new to the software, it is highly recommended that they adhere to the default setting parameters and follow the step-by-step procedure meticulously to ensure accurate results. It is important to note that variations in hardware and software configurations may yield slight differences in the obtained results.

This Tutorial Manual does not provide the theoretical background information on the SPH method or elaborate on the specific details of the constitutive models utilised within the software. Therefore, users are highly advised to refer to the provided references for comprehensive information regarding the SPH method and constitutive models implemented in GeoXPM. These references offer in-depth insights into the underlying principles and methodologies employed, allowing users to gain a thorough understanding of the theoretical aspects involved. Example:

3D Hourglass

In this project, you will learn about using:

- External Mesh objects
- "FillBox" tool
- Creating a basic **rendering** with path tracing.

We will follow the below standard workflow:

- 1. Create a new project.
- 2. Create initial geometry.
- 3. Input SPH parameters.
- 4. Create material models.
- 5. Include objects in simulations and assign material properties.
- 6. Define construction stages.
- 7. Define meshing sequences.
- 8. Mesh objects generate particles for calculations.
- 9. Calculate.
- 10. Post-processing Visualisation: extract, data mining.

> Step 1. Create a new project

- a. Click the "New Project" button in the dialogue below to create a new project.
- b. Enter the project name and project description.

		→ Start	
🚫 Project and constant definition		?	×
Project Name: Project Description: Hourglass project using imported 3D STL mesh	3DHourglass		
Gravity (m/s²): Fluid reference density (kg/m³):	-9.81		

> Step 2. Create initial geometry

a. Using the "Import Terrain" tool to import the mesh file for the hourglass.

Imported object name: Hourglass	
	Cancel Import

b. Using the "FillBox" tool to fill half of the hourglass with **sand** particles. "Fillpoint" is placed inside the top half of the hourglass, and "Filllimit" is set to a desired height.

FillPoint

FillLimit

Hint: For moving an object in 3D space. You can select the object and then go to Edit -> Transform to drag the object around.

> Step 3. Input SPH parameters

a. Enter the SPH parameters into the dialogue.

	ſ,
Interaction kernel:	Cubic spline ~
Approximation algorithm:	Type 2: $\sigma_i/\rho_i^2 + \sigma_j/\rho_j^2$ \sim
Particle distance (m):	0.0018
Critical timestep factor (CFL):	0.2
Time out data (iter):	300.0
Adaptive simulation domain:	
Load initial stress:	Browse
Artificial stress	_
Enabled:	
Epsi coefficient:	0.5
Particle shifting	
Detection algorithm:	Kernel gradient
Eree surface threshold (<-1) :	
	2.0
Diffusion coefficient:	2.0
Artificial viscosity	0.1
Alpha coefficient:	0.1
Beta coefficient:	0
Eta _q coefficient:	0.1
Autostop: (For plastic Stage)	
Enabled:	\bowtie

> Step 4. Input material properties

a. Click the "Material Properties" button, select the appropriate constitutive model (i.e., $\mu(I)$ Rheology model) provided in the "New material" button, and enter the material parameters.

Materials configuration		?	×
Materials	Material Properties		
New Material Sand	Model: Unit Weight (kg/m3): Constitutive parameter mu_s: Constitutive parameter mu_p: Grain diameter (m): Material constant I0: Sound speed (m/s): Density diffusion coefficient:	Muil 2000.0 0.58 1.19 0.01 2.65 6.5 0.0	

Hint: The timestep for the $\mu(I)$ model depends heavily on the sound speed. Setting it low makes the simulation faster but risks extreme particle overlapping and penetration. A good initial estimation for the sound speed can be induced from the maximum velocity of a free fall body ($v=\sqrt{2gH_{max}}$) times a factor of 2 to 3.

Step 5. Include objects in simulations and assign material properties

- a. Soil object: Select the "Sand" in the "Model" tab and click "Add to Simulation" under the "GeoXPM" tab. And then, select the "Type of object" as "Soil". In the next step, click the "Assign" button to assign the "Sand" model to the soil in the dialogue of the material configuration.
- b. Boundary object: Repeat the above process for "Hourglass", "Edge", and "Bottom" objects; however, keep "Type of object" as Boundary.

	ОК		

Meshing order configuration

Hint: Fillbox will fill only work after meshing a container.

> Step 8. Generate particles for computations

- a. Before meshing, click the "Save" button (¹) to save the project as 2D or 3D based on your need.
- b. Click the "Autofit simulation domain" button to fit all simulated objects in the calculation domain.
- c. Click the "Generate particles" tool to mesh the computational domain

d. After meshing, click "Open with Paraview" to view the particle configuration.

Hint: Typically, SPH boundaries require a minimum of 2-3 consecutive layers to be effective. Inadequate thickness of the boundaries can result in them being penetrated.

> Step 9. Start the Calculation

Click the "Run" button and start the calculations.

S GeoXPM Simulation: 0%	? ×	
Simulation Data Case name: Hourglass3D Total number of particles: 350776		
Estimated time to complete simulation: Calculating		
	Details Cancel Simulation	1

Step 10. Visualisation

- a. Click on the tool "Export output data to VTU format" to start exporting data to Paraview anytime during the simulation or after completion.
- b. When the export is done, Paraview will open with already imported results. All the data can be customised and visualised from here.

Hint: If you activate the "Adaptive simulation domain" in step 3, the simulation will only generate particles around the soil domain.

To create a rendering result. We can make use of Paraview textures and path-tracing algorithms.

- a. In ParaView, click the eye icon next to Boundaries in the "pipeline Browser" to hide Boundaries particles.
- b. Click "Open" button () and go to the "*_out" folder of the project, and open the "*__Actual.vtk" object.

c. Go to "View" Menu \rightarrow Material Editor to activate the "Material Editor" tab.
